Abstract. Proposes a textual programming language that enables conceptual modeling (similarly to UML classes/associations and OCL constraints) and a compiler that allows code generation (via extensible textual templates) to any target language or technology. Together, the language and the compiler make it feasible to specify (in a single high-level language) the information of ever-changing, increasingly distributed software systems. From this single source, the automated code generation keeps the implementations (across the different platforms and technologies) consistent with the specification. Also, as the technology landscape evolves, these textual models allow the recurring use of the investment made on their specification. Unlike other approaches, such as MDA and MPS, the built-in tooling support, along with the textual nature of this programming language and its extensible templates, facilitates the integration to the workflow of software developers, which is expected to promote its adoption.

1 Introduction

In order to address the challenges of the ever-changing, increasingly distributed technologies used on software systems, the Model-Driven Architecture (MDA [1]) initiative by the Object Management Group (OMG) has been promoting model-driven software development. In particular, MDA has guided the use of high-level models (created with OMG standards, such as UML [3], OCL [2] and MOF [4]) to derive software artifacts and implementations via automated transformations. As one of its value propositions, the MDA guide [1] advocates:

“Automation reduces the time and cost of realizing a design, reduces the time and cost for changes and maintenance and produces results that ensure consistency across all of the derived artifacts. For example, manually producing all of the web service artifacts required to implement a set of processes and services for an organization is difficult and error-prone. Producing execution artifacts from a model is more reliable and faster.”

Even though MDA provides guidance and standards that can be used to realize its vision, it leaves to software vendors the task of providing the tools that automate the process of generating the implementations from the models.

The key role played by tools has been demonstrated by Voelter [5] in his *Generic Tools, Specific Languages* approach for model-driven software development. In his approach, Voelter [5] has used domain-specific languages (DSL's) with the Metaprogramming System (MPS) in order to generate the software artifacts. Unlike MDA, which is based on UML/MOF models, MPS allows the specification of models using domain-specific editors. MPS itself is a generic tool, but it enables the definition of the abstract syntax, the editors and the code generators for DSL's.
